Sidrabe Inc., Krustpils str. 17, Riga, LV-1073, LATVIA

Problem
Lithium (Li) metal is an ideal anode material for rechargeable batteries due to its extremely high theoretical specific capacity (3860 mA h g⁻¹), low density (0.59 g cm⁻³) and the lowest negative electrochemical potential (−3.040 V vs. the standard hydrogen electrode). Unfortunately, uncontrollable dendritic Li growth and limited Coulombic efficiency during Li deposition/stripping inherent in these batteries have prevented their practical applications over the past 40 years. With the emergence of post-Li-ion batteries, safe and efficient operation of Li metal anodes has become an enabling technology which may determine the fate of several promising candidates for the next generation energy storage systems, including rechargeable Li-air batteries, Li–S batteries, and Li metal batteries which utilize intercalation compounds as cathodes [1].

Benefits of ultra-thin metal anode

Using of metallic anode allows decrease of total cell volume almost twice. Conventional anodes are produced with rolling methods and anode thickness is up to 40 microns. Physical vapour deposition (PVD) in vacuum makes it possible to have anode thickness of several microns.

PVD method allows deposition of 1...20 microns thick Lithium layer in one pass onto thin metallic foils or metallized polymer films. Since Lithium is deposited in high vacuum (1*10⁻⁵ Torr), it comes out in a «pure» state: vacuum deposited Lithium has minimal oxide layers. Lithium batteries hence benefit by high levels of purity.

Coating deposition conditions provide high Lithium surface activity, what is inaccessible for traditional rolling.

Additional benefit of PVD processing is low cost as less metal is required.

Capabilities of PVD Lithium coating equipment in Sidrabe laboratory

Sidrabe has research and development areas for Li coating investigation and samples manufacturing under contracts with potential customers. We have two Sidrabe made laboratory roll-to-roll Li coaters associated with Dry room. Coated material is transferred into glove box where it is packaged into sealed metal-polymeric bags filled with Argon.
